1 Objective

To determine the process for the 2022 Southeast Alaska (SEAK) preseason pink salmon forecast using data through 2020.

2 Executive Summary

Forecasts were developed using an approach originally described in Wertheimer et al. (2006), and modified in Orsi et al. (2016) and Murphy et al. (2019). We used a similar approach to Murphy et al. (2019), but assumed a log-normal error. This approach is based on a multiple regression model with juvenile pink salmon catch-per-unit-effort (CPUE) and temperature data from the Southeast Alaska Coastal Monitoring Survey (SECM; Murphy et al. 2020) or satellite sea surface temperature data (SST and SST Anomaly, NOAA Global Coral Bleaching Monitoring, 5km, V.3.1, Monthly, 1985-Present' time series (https://coastwatch.pfeg. noaa.gov/erddap/griddap/NOAA_DHW_monthly.html). Based on prior discussions, the index of juvenile abundance (i.e., CPUE) was based on the pooled-species vessel calibration coefficient.

Leave-one-out cross validation (hindcast) and model performance metrics were used to evaluate the forecast accuracy of models. These metrics included Akaike Information Criterion corrected for small sample sizes (AICc values; Burnham and Anderson 2004), the mean absolute scaled error (MASE metric; Hyndman and Kohler 2006), the weighted mean absolute percentage error (wMAPE; based on the last 5 years), leave one out cross validation MAPE ($MAPE_LOOCV$), and significant coefficients (i.e., covariates) in the model.

3 Analysis

3.1 Hierarchical models

Forty five hierarchical models were investigated. The full model was:

$$E(y) = \alpha + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_1 X_2,$$

where X_1 is the average CPUE for catches in either the June or July survey, whichever month had the highest average catches in a given year, and was based on the pooled-species vessel calibration coefficient, X_2 is a temperature index, and β_3 is the interaction term between CPUE and a temperature index. The CPUE data were log-transformed in the model, but temperature data was not. The simplest model did not contain a temperature variable (model m1 or 1). None of the interactions were significant (see Appendix); therefore only additive models (23 models) were considered further.

Table 1: Parameter estimates for the 23 potential models.

3.2 Performance Metrics

The model summary results using the performance metrics AICc, MASE, wMAPE, and $MAPE_LOOCV$ are shown in Table 2. For all of these metrics, the smallest value is the preferred model. Models with $\Delta_i AICc \leq 2$ have substantial support, those in which $4 \leq \Delta_i AICc \leq 7$ have considerably less support, and models with $\Delta_i AICc > 10$ have essentially no support (Burnham and Anderson 2004). The performance metric MAPE was calculated as

$$MAPE = \frac{1}{n} \sum_{t=1}^{n} \left| \frac{A_t - F_t}{A_t} \right|$$

where A_t is the observed values and F_t are the predicted values. The performance metric wMAPE was calculated as

$$wMAPE = \sum_{t=1}^{n} \frac{1}{w_t} \sum_{t=1}^{n} \left| \frac{A_t - F_t}{A_t} \right| w_t.$$

The AICc in Table 2 is the AICc value and not the Δ_i AICc. The performance metric AICc suggests that models m19, m16, and m13 are the recommended models. The performance metrics MASE and $MAPE_LOOCV$ suggest that models m16, m22, m19 and m13 are the recommended models. The performance metric wMAPE suggests that models m20, m16, m22, and m19 are the recommended models.

Table 2: Summary of model outputs and forecast error measures. These metrics included Akaike Information Criterion corrected for small sample sizes (AICc values), the mean absolute scaled error (MASE metric), the weighted mean absolute percentage error (wMAPE; based on the last 5 years), and leave one out cross validation MAPE (MAPE_LOOCV).

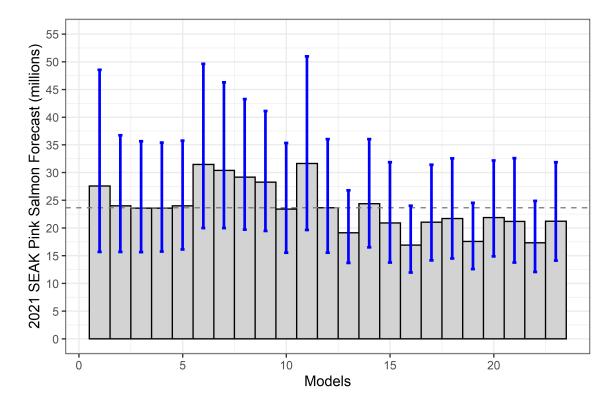

Figure 1: The 2021 SEAK pink salmon harvest (millions) forecast by model. The 80% prediction intervals (corrected for log transformation bias in a linear-model) around each forecast were calculated using the car package (Fox and Weisberg 2019) in program R (R Core Team 2020). The dotted horizontal line is the average forecast across all models. The SEAK pink salmon harvest in 2021 (based on the November 18, 2020 advisory announcement) was a point estimate of 28 million fish (80% prediction interval: 19–42 million fish).
